DESCRIPTION

IMAGE PROCESSING APPARATUS, IMAGE PROCESSING METHOD, PROGRAM
FOR IMAGE PROCESSING METHOD, AND RECORDING MEDIUM RECORDING
THEREON PROGRAM FOR IMAGE PROCESSING METHOD

5

Technical Field

The present invention relates to image progressing
apparatuses, image processing methods, programs for image
processing methods, and recording media recording thereon
10 programs for image processing methods, and is applicable,
for example, to resolution conversion. The present
invention is capable of effectively avoiding loss of high-
frequency components and preventing occurrence of jaggies by
detecting an edge gradient direction with the largest
15 gradient of pixel values and an edge direction orthogonal to
the edge gradient direction and by performing edge
enhancement and smoothing processing in the edge gradient
direction and in the edge direction, respectively, to
generate output image data.

20

BACKGROUND OF THE INVENTION

Background Art

In image processing, resolution conversion has been
performed, for example, by linear interpolation or bicubic
25 conversion. A method for performing such image processing

with a simplified configuration is proposed, for example, in Japanese Unexamined Patent Application Publication No. 2003-224715.

However, in such image processing, jaggies occur in
5 edge portions. When a characteristic of linear
interpolation or bicubic conversion is set such that jaggies
do not stand out, there is a problem that high-frequency
components of an image are lost and that the image is
blurred due to a reduction in the sharpness. Since
10 considerable image blur occurs in texture portions, the
characteristic of such processing may be changed in the
texture portions. However, in this case, heterogeneity and
flickering occur in positions where the characteristic is
changed.

15

Disclosure of Invention

The present invention is designed in view of the
foregoing points, and proposes an image processing apparatus,
an image processing method, a program for an image
20 processing method, and a recording medium recording thereon
a program for an image processing method that are capable of
effectively avoiding loss of high-frequency components and
preventing occurrence of jaggies.

In order to solve the above problems, the present
25 invention is applied to an image processing apparatus for

processing input image data and for outputting output image data. The image processing apparatus includes an edge detection unit for detecting an edge gradient direction with the largest gradient of pixel values and an edge direction
5 orthogonal to the edge gradient direction for each pixel of the input image data; an edge direction processing unit for performing smoothing processing on the image data in the edge direction for each pixel of the output image data in accordance with a detection result of the edge detection
10 unit and for sequentially detecting pixel values corresponding to respective pixels of the output image data; and an edge gradient direction processing unit for performing edge enhancement processing in the edge gradient direction on the pixel values output from the edge direction
15 processing unit for the respective pixels of the output image data in accordance with the detection result of the edge detection unit and for sequentially outputting pixel values of the output image data.

The configuration according to the present invention is
20 applied to an image processing apparatus for processing input image data and for outputting output image data. The image processing apparatus includes an edge detection unit for detecting an edge gradient direction with the largest gradient of pixel values and an edge direction orthogonal to
25 the edge gradient direction for each pixel of the input

image data; an edge direction processing unit for performing smoothing processing on the image data in the edge direction for each pixel of the output image data in accordance with a detection result of the edge detection unit and for
5 sequentially detecting pixel values corresponding to respective pixels of the output image data; and an edge gradient direction processing unit for performing edge enhancement processing in the edge gradient direction on the pixel values output from the edge direction processing unit
10 for the respective pixels of the output image data in accordance with the detection result of the edge detection unit and for sequentially outputting pixel values of the output image data. Thus, edge enhancement and smoothing processing are performed in the edge gradient direction with
15 the largest gradient of pixel values and in the edge direction orthogonal to the edge gradient direction, respectively, to generate the output image data. Therefore, loss of high-frequency components can be effectively avoided, and occurrence of jaggies can be prevented.

20 In addition, the present invention is applied to an image processing method for processing input image data and for outputting output image data. The image processing method includes an edge detection step of detecting an edge gradient direction with the largest gradient of pixel values
25 and an edge direction orthogonal to the edge gradient

direction for each pixel of the input image data; an edge
direction processing step of performing smoothing processing
on the image data in the edge direction for each pixel of
the output image data in accordance with a detection result
5 by the edge detection step and sequentially detecting pixel
values corresponding to respective pixels of the output
image data; and an edge gradient direction processing step
of performing edge enhancement processing in the edge
gradient direction on the pixel values detected by the edge
10 direction processing step for the respective pixels of the
output image data in accordance with the detection result by
the edge detection step and sequentially outputting pixel
values of the output image data.

Thus, with the configuration according to the present
15 invention, an image processing method capable of effectively
avoiding loss of high-frequency components and preventing
occurrence of jaggies can be provided.

In addition, the present invention is applied to a
program for an image processing method performed by
20 arithmetic processing means for processing input image data
and for outputting output image data. The program includes
an edge detection step of detecting an edge gradient
direction with the largest gradient of pixel values and an
edge direction orthogonal to the edge gradient direction for
25 each pixel of the input image data; an edge direction

processing step of performing smoothing processing on the
image data in the edge direction for each pixel of the
output image data in accordance with a detection result by
the edge detection step and sequentially detecting pixel
5 values corresponding to respective pixels of the output
image data; and an edge gradient direction processing step
of performing edge enhancement processing in the edge
gradient direction on the pixel values detected by the edge
direction processing step for the respective pixels of the
10 output image data in accordance with the detection result by
the edge detection step and sequentially outputting pixel
values of the output image data.

Thus, with the configuration according to the present
invention, a program for an image processing method capable
15 of effectively avoiding loss of high-frequency components
and preventing occurrence of jaggies can be provided.

In addition, the present invention is applied to a
recording medium recording thereon a program for an image
processing method performed by arithmetic processing means
20 for processing input image data and for outputting output
image data. The program for the image processing method
includes an edge detection step of detecting an edge
gradient direction with the largest gradient of pixel values
and an edge direction orthogonal to the edge gradient
25 direction for each pixel of the input image data; an edge

direction processing step of performing smoothing processing
on the image data in the edge direction for each pixel of
the output image data in accordance with a detection result
by the edge detection step and sequentially detecting pixel
5 values corresponding to respective pixels of the output
image data; and an edge gradient direction processing step
of performing edge enhancement processing in the edge
gradient direction on the pixel values detected by the edge
direction processing step for the respective pixels of the
10 output image data in accordance with the detection result by
the edge detection step and sequentially outputting pixel
values of the output image data.

Thus, with the configuration according to the present
invention, a recording medium recording thereon a program
15 for an image processing method capable of effectively
avoiding loss of high-frequency components and preventing
occurrence of jaggies can be provided.

According to the present invention, loss of high-
20 frequency components can be effectively avoided and
occurrence of jaggies can be prevented.

Brief Description of the Drawings

20 Best Mode for Carrying Out the Invention

Embodiments of the present invention will be described by appropriately referring to the drawings.

(1) Configuration of Embodiment

Fig. 1 is a functional block diagram showing an image
25 processing apparatus according to an embodiment of the

present invention. The image processing apparatus 1 is formed by, for example, a digital signal processor functioning as arithmetic processing means. By a predetermined processing program performed by the arithmetic
5 processing means, the resolution of image data D1, which is input image data, is converted into a resolution designated by a controller, which is not shown, and the converted image data is output. Accordingly, the image processing apparatus 1 generates output image data D2 obtained by magnifying or
10 reducing an image based on the image data D1, and outputs the generated output image data D2 to displaying means or the like.

Although the processing program for the arithmetic processing means is supplied by being pre-installed in the
15 image processing apparatus in this embodiment, for example, such a processing program may be supplied by being downloaded via a network, such as the Internet, or may be supplied via various recording media. Such recording media may be widely applicable to various recording media, such as
20 optical disks, memory cards, and detachable hard disk drives.

In the image processing apparatus 1, an edge detection unit 2 detects an edge gradient direction with the largest gradient of pixel values and an edge direction orthogonal to the edge gradient direction for each pixel of the image data
25 D1. In other words, in the edge detection unit 2, a

gradient matrix generation unit 3 sequentially selects a target pixel, for example, in a raster scanning order, and, as shown in Fig. 2, generates a brightness gradient matrix G represented by the next condition by performing arithmetic processing using pixel values in a range W centered on the target pixel. Fig. 2 shows an example in which ± 3 pixels in x and y directions centered on a target pixel are set as the range W.

$$\begin{aligned}
 G &= \int_W g g^T w dA \\
 &= \sum_W \begin{pmatrix} g_x^{(i,i)} g_x^{(i,i)} w^{(i,i)} & g_x^{(i,i)} g_y^{(i,i)} w^{(i,i)} \\ g_y^{(i,i)} g_x^{(i,i)} w^{(i,i)} & g_y^{(i,i)} g_y^{(i,i)} w^{(i,i)} \end{pmatrix} \\
 &\equiv \begin{pmatrix} G_{xx} & G_{xy} \\ G_{yx} & G_{yy} \end{pmatrix}
 \end{aligned}
 \tag{1}$$

In addition, " $w^{(i,j)}$ " represents a Gaussian weight represented by condition (2), and "g" represents a brightness gradient represented by condition (3) using a partial differential "gx" in the x direction of an image brightness I and a partial differential "gy" in the y direction of the image brightness I.

$$w^{(i,j)} = e^{-\frac{i^2 + j^2}{2\sigma^2}}
 \tag{2}$$

$$g = (g_x, g_y)$$

$$= \left(\frac{\partial I}{\partial x}, \frac{\partial I}{\partial y} \right) \quad \text{..... (3)}$$

Accordingly, in the edge detection unit 2, the gradient matrix generation unit 3 detects a brightness gradient obtained by weighting based on a target pixel in the
5 predetermined range W centered on the target pixel.

In the edge detection unit 2, a subsequent eigenvalue and eigenvector detection unit 4 detects an edge gradient direction v1 with the largest gradient of pixel values and an edge direction v2 orthogonal to the edge gradient
10 direction v1 for a target pixel, as shown in Fig. 3, by processing the brightness gradient matrix G generated by the gradient matrix generation unit 3. In addition, the eigenvalue and eigenvector detection unit 4 detects eigenvalues λ1 and λ2 representing dispersions of gradients
15 of the pixel values in the edge gradient direction v1 and in the edge direction v2, respectively.

More specifically, the eigenvalue and eigenvector detection unit 4 detects the edge gradient direction v1, the edge direction v2, and the eigenvalues λ1 and λ2 (λ1 ≥ λ2) in
20 accordance with the following arithmetic processing:

$$\lambda_1 = \frac{G_{xx} + G_{yy} + \sqrt{a}}{2} \quad \text{..... (4)}$$

$$\lambda_2 = \frac{G_{xx} + G_{yy} - \sqrt{a}}{2} \quad \text{..... (5)}$$

$$v1 = \frac{v'1}{\|v'1\|}$$

$$v'1 = \left(\frac{G_{xx} - G_{yy} + \sqrt{a}}{2 G_{xy}}, 1 \right) \quad \dots (6)$$

$$v2 = \frac{v'2}{\|v'2\|}$$

$$v'2 = \left(\frac{G_{xx} - G_{yy} - \sqrt{a}}{2 G_{xy}}, 1 \right) \quad \dots (7),$$

5 where "a" is defined by the following condition:

$$a = G_{xx}^2 + 4 G_{xy}^2 - 2 G_{xx} G_{yy} + G_{yy}^2 \quad \dots (8).$$

An edge direction processing unit 5 calculates an edge direction vc for a pixel of the image data D2 acquired after resolution conversion in accordance with the edge direction
 10 v2 for a target pixel of the image data D1 detected as described above by the edge detection unit 2, and sequentially calculates a pixel value corresponding to each pixel Pc of the output image data D2 by interpolation processing based on the edge direction vc.

15 In other words, as shown in Fig. 4, the edge direction processing unit 5 performs arithmetic processing based on the next condition for pixels of the image data D1 (in the example shown in Fig. 4, P3, P4, P9, and P10) adjacent to a

pixel Pc of the output image data D2 to be calculated
(hereinafter, referred to as a target pixel of the image
data D2), and calculates the edge direction vc of the target
pixel Pc by performing interpolation processing using the
5 edge directions v2 (v3, v4, v9, and v10) of the adjacent
pixels of the image data D1.

$$v_c = (1 - t_y) \{ (1 - t_x) v_3 + t_x v_4 \} + t_y \{ (1 - t_x) v_9 + t_x v_{10} \}$$

.....(9)

Here, "tx" and "ty" represent coordinate values of a
10 target pixel for internally dividing the sampling points P3,
P4, P9, and P10 based on the image data D1 in the x and y
directions, and the conditions $0 \leq t_x \leq 1$ and $0 \leq t_y \leq 1$ are
satisfied.

In addition, in accordance with the edge direction vc
15 for the target pixel Pc calculated as described above, the
edge direction processing unit 5 sets a predetermined number
of sampling points P-2, P-1, P1, and P2 based on a sampling
pitch in the image data D1 from the sampling points for the
target pixel Pc on a line in the edge direction vc. In
20 addition, pixel values of the sampling points P-2, P-1, P1,
and P2 and the target pixel Pc are calculated by an
interpolation operation using pixel values of the image data
D1. Accordingly, in accordance with detection results of
the edge detection unit 2, interpolated image data in the

edge direction based on interpolation processing for the input image data D1 is generated on the line extending in the edge direction vc for each pixel of the output image data D2.

5 In addition, in accordance with a calculation result of an edge direction range determination unit 6, which will be described below, the number of sampling points set as described above is changed, and the subsequent filtering processing is changed. Thus, the number of taps for the
10 filtering processing is changed in accordance with reliability of an edge in the edge direction vc of the target pixel. More specifically, for example, in a case where the subsequent filtering processing is performed based on 3-tap filtering, a pixel value of the target pixel Pc is
15 calculated by linear interpolation using the peripheral pixels P3, P4, P9, and P10, and pixel values of the previous and subsequent sampling points P-1 and P1 are calculated by linear interpolation using P2, P3, P8, and P9; and P4, P5, P10, and P11, respectively. In contrast, in a case where
20 the subsequent filtering processing is performed based on 5-tap filtering, a pixel value of the target pixel Pc is calculated by linear interpolation using the peripheral pixels P3, P4, P9, and P10, and pixel values of the sampling points P-2, P-1, P1, and P2 are calculated in a similar way.
25 Then, the edge direction processing unit 5 smoothes the

calculated pixel values of the sampling points P-2, P-1, P1, and P2 and the target pixel Pc by filtering processing, and determines a pixel value Pc' of the target pixel Pc. In other words, for 3-tap filtering, for example, the pixel
5 value Pc' of the target pixel Pc is calculated by arithmetic processing represented by the following condition:

$$P'_c = 0.25 \times P_{-1} + 0.5 \times P_c + 0.25 \times P_{+1} \quad \text{.....(10).}$$

In contrast, for 5-tap filtering, for example, the pixel value Pc' of the target pixel Pc is calculated by
10 arithmetic processing represented by the following condition:

$$P'_c = 0.0625 \times P_{-2} + 0.25 \times P_{-1} + 0.375 \times P_c \\ + 0.25 \times P_{+1} + 0.0625 \times P_{+2} \quad \text{.....(11).}$$

As described above, in this embodiment, a pixel value
15 corresponding to a pixel of the output image data D2 is calculated by performing smoothing processing on interpolated image data in an edge direction. Thus, loss of high-frequency components can be effectively avoided and occurrence of jaggies in an edge can be prevented. In
20 addition, an interpolation operation for generating such interpolated image data need not be linear interpolation using pixel values of adjacent neighboring pixels, and various interpolation operation methods using various

peripheral pixels are widely applicable. In addition,
arithmetic processing for filtering processing using the
interpolated image data need not be the arithmetic
processing based on condition (10) or (11), and
5 interpolation operations using various weighting
coefficients are widely applicable.

In a case where pixel values in the image data D2 are
calculated by detecting edge directions for respective
pixels as described above, smoothing processing may be
10 performed in a direction orthogonal to a brightness gradient
in a portion other than an edge. In such a case, if
filtering processing is performed with a large number of
taps involving a wide range, an image quality is reduced.
In contrast, however, in an edge portion, filtering
15 processing performed in a wide range prevents occurrence of
jaggies more reliably and thus forms a smooth edge.

Thus, in this embodiment, the number of taps for
filtering processing is changed for each pixel. Thus, a
range for smoothing processing in an edge direction is
20 changed for each pixel. In addition, such a filtering range
is changed in accordance with reliability of an edge in the
edge direction v_c . Therefore, a reduction in the image
quality due to smoothing processing can be prevented.

More specifically, in this embodiment, in accordance
25 with the ratio λ_2/λ_1 of the eigenvalue λ_2 for the edge

direction v_2 to the eigenvalue λ_1 for the edge gradient direction v_1 , reliability of an edge in the edge direction v_c is detected. In other words, if the ratio λ_2/λ_1 is small, it is determined that the pixel value gradient in the edge gradient direction v_1 is predominant in this target pixel and that a stronger edge appears in the edge direction v_2 . Thus, as shown in Fig. 5, the edge direction processing range determination unit 6 generates a parameter p that increases substantially linearly in accordance with a decrease in the value of the ratio λ_2/λ_1 when the ratio λ_2/λ_1 is within a predetermined range between λ_2/λ_{1min} and λ_2/λ_{1max} and that exhibits the maximum value p_{max} or the minimum value p_{min} when the ratio λ_2/λ_1 is outside the predetermined range between λ_2/λ_{1min} and λ_2/λ_{1max} . Accordingly, the parameter p changing depending on reliability of an edge in an edge direction is generated.

If the eigenvalue λ_1 for the edge gradient direction v_1 is large, the contrast across the edge is large. Thus, this edge is regarded as being a distinctive edge. Thus, as shown in Fig. 6, the edge direction processing range determination unit 6 generates a parameter q that increases substantially linearly in accordance with the eigenvalue λ_1 in a predetermined range between λ_{1min} and λ_{1max} and that exhibits a lower limit value q_{min} or an upper limit value q_{max} in a range smaller or larger than the range between λ_1

min and λ_{max} . Accordingly, the parameter q changing in accordance with rising of an edge is generated.

The edge direction processing range determination unit 6 performs multiplication represented by the next condition for the two parameters p and q to calculate a filtering range r for the edge direction processing.

$$r = p \times q \quad \text{.....(12)}$$

In order to correspond to the sampling points of the image data D_2 in the processing of the edge direction processing unit 5, the edge direction processing range determination unit 6 converts the eigenvalues λ_1 and λ_2 based on the sampling points of the image data D_1 into eigenvalues based on the sampling points of the image data D_2 , and calculates a filtering range r . In this case, after a filtering range r is calculated from the sampling points of the image data D_1 , a filtering range r based on the sampling points of the image data D_2 may be calculated by interpolation processing for the calculation result. In contrast, after the eigenvalues λ_1 and λ_2 based on the sampling points of the image data D_2 are calculated by interpolating the eigenvalues λ_1 and λ_2 based on the sampling points of the image data D_1 , a filtering range r based on the sampling points of the image data D_2 may be calculated from the calculation result.

Accordingly, the edge direction processing unit 5

changes the number of taps for the filtering processing in accordance with the range r calculated as described above, and calculates the pixel value Pc' of the target pixel Pc of the image data $D2$.

5 In such filtering processing, the edge direction processing unit 5 performs filtering processing based on the real number of taps by blending filtering processing results. Thus, the edge direction processing unit 5 overcomes
unnaturalness in changing the number of taps when the
10 filtering processing is performed based on the integral number of taps.

 In other words, in the edge direction processing unit 5, a filter with the integral number of taps represented by the next condition is defined. Here, an odd number, such as 1,
15 3, 5,, is applied as the integral number of taps.

$$n_{integer}^{-1} = \text{floor}(n_{real})$$

$$n_{integer}^{+1} = \text{ceil}(n_{real})$$

.....(13)

 Here, "floor(n)" represents the maximum integral number of taps not exceeding n , and "ceil(n)" represents the
20 minimum integral number of taps larger than n . In addition, the range r calculated based on condition (12) is applied to " n_{real} ". Thus, when n is 3.5, the number of taps
"floor(n)" is 3, and the number of taps "ceil(n)" is 5.

 Blending of the filtering processing results is

performed by calculating a filtering processing result $f(n)$ based on a real number by performing arithmetic processing represented by the next condition using the two types of filtering processing results. Thus, the edge direction processing unit 5 calculates the pixel value Pc' of the target pixel Pc of the image data $D2$ by performing filtering processing based on the two types of tap numbers in the filtering range r and by further performing arithmetic processing represented by condition (14) using the two types of filtering processing results. Accordingly, the edge direction processing unit 5 calculates the pixel value Pc' of the target pixel Pc of the image data $D2$ by performing filtering processing based on the number of taps corresponding to reliability of an edge in an edge direction, and changes the number of taps in a decimal fractional part.

$$f(n) = \alpha f(n_{integer}^{-1}) + (1 - \alpha) f(n_{integer}^{+1}) \quad \text{..... (14)}$$

$$\text{here, } \alpha = (n_{integer}^{+1} - n_{real}) / 2$$

An edge gradient direction processing unit 7 performs edge enhancement processing in the edge gradient direction $v1$ using the pixel value Pc' of the target pixel Pc of the image data $D2$ calculated as described above by the edge direction processing unit 5. In other words, as shown in Fig. 7, the edge gradient direction processing unit 7

calculates an edge gradient direction vg for a target pixel P_{cc} of the image data $D2$ in accordance with the edge gradient direction vl based on adjacent sampling points of the image data $D1$, as in calculation of the edge direction vc for the target pixel Pc of the image data $D2$ performed by the edge direction processing unit 5.

In addition, in accordance with the edge gradient direction vg for the target pixel P_{cc} calculated as described above, the edge gradient direction processing unit 7 sets a predetermined number of sampling points P_{c-1} and P_{c+1} based on a sampling pitch in the image data $D2$ from the sampling points for the target pixel P_{cc} on a line in the edge gradient direction vg . In addition, the edge gradient direction processing unit 7 calculates pixel values of the sampling points P_{c-1} and P_{c+1} and the target pixel P_{cc} by an interpolation operation using pixel values output from the edge direction processing unit 5. Accordingly, in accordance with detection results of the edge detection unit 2, the edge gradient direction processing unit 7 generates interpolated image data in the edge gradient direction obtained by interpolation processing for the image data based on the pixel values output from the edge direction processing unit 5 on a line extending in the edge gradient direction vg for each pixel of the output image data $D2$.

Then, the edge gradient direction processing unit 7

performs filtering processing on the pixel values of the sampling points P_{c-1} and P_{c+1} and the target pixel P_{cc} calculated as described above, and determines a pixel value P_{cc}' of the target pixel P_{cc} . In the example shown in Fig. 5 7, a case where the pixel value P_{cc}' of the target pixel P_{cc} is calculated using three taps is described. The pixel value of the sampling point P_{c-1} is generated by linear interpolation based on peripheral sampling points P_{c1} , P_{c2} , P_{c4} , and P_{cc} , and the pixel value of the sampling point P_{c+1} 10 is generated by linear interpolation based on peripheral sampling points P_{cc} , P_{c5} , P_{c7} , and P_{c8} . Accordingly, the edge gradient direction processing unit 7 performs edge enhancement in the direction that crosses the edge. In such an interpolation operation for generating interpolated image 15 data, linear interpolation using pixel values of adjacent neighboring pixels need not be performed, and interpolation operation methods using various peripheral pixels are widely applicable. In addition, as arithmetic processing for filtering processing using such interpolated image data, 20 interpolation operations using various weighting coefficients are widely applicable.

An interpolation processing unit 8 converts a resolution of the image data $D1$, for example, by linear interpolation or bicubic conversion, and outputs a pixel 25 value P_a based on a sampling pitch corresponding to the

image data D2.

A blend ratio determination unit 9 generates a weighting coefficient for blending in accordance with reliability of an edge in the edge direction v_c . In other words, when smoothing processing is performed in the edge direction and edge enhancement is performed in a direction orthogonal to the edge, unnatural edge enhancement may occur in a natural image. Thus, in this embodiment, a blend processing unit 10 performs weighting addition of the pixel value P_a of the image data D2 generated by the interpolation processing unit 8 using a known procedure and the pixel value $P_{cc'}$ generated by the edge gradient direction processing unit 7 in order to generate the image data D2, and the blend ratio determination unit 9 changes the weighting coefficient for the weighting addition processing. In addition, the blend ratio determination unit 9 changes the weighting coefficient in accordance with reliability of an edge in an edge direction, and this prevents excessive unnaturalness in processing for the edge. In addition, the ratio λ_2/λ_1 of the eigenvalue λ_2 for the edge direction v_2 to the eigenvalue λ_1 for the edge gradient direction v_1 is applied to the reliability of the edge in the edge direction.

More specifically, if the ratio λ_2/λ_1 is small, it is determined that the gradient in the edge gradient direction v_1 is predominant in this target pixel and that a stronger

edge appears in the edge direction v_2 . Thus, as shown in Fig. 8, the blend ratio determination unit 9 generates a parameter s that increases substantially linearly in accordance with a decrease in the value of the ratio λ_2/λ_1 when the ratio λ_2/λ_1 is within a predetermined range between λ_2/λ_{1min} and λ_2/λ_{1max} and that exhibits the maximum value s_{max} or the minimum value s_{min} when the ratio λ_2/λ_1 is outside the predetermined range between λ_2/λ_{1min} and λ_2/λ_{1max} . Accordingly, the parameter s changing depending on reliability of an edge in an edge direction is generated.

If the eigenvalue λ_1 for the edge gradient direction v_1 is large, the contrast across the edge is large. Thus, this edge is regarded as being a distinctive edge. Thus, as shown in Fig. 9, the blend ratio determination unit 9 generates a parameter t that increases substantially linearly in accordance with the eigenvalue λ_1 in a predetermined range between λ_{1min} and λ_{1max} and that exhibits a lower limit value t_{min} or an upper limit value t_{max} in a range outside the range between λ_{1min} and λ_{1max} . Accordingly, the parameter t changing in accordance with rising of an edge is generated.

The blend ratio determination unit 9 performs multiplication represented by the next condition for the two parameters s and t to calculate a weighting coefficient β for blending ($0 \leq \beta \leq 1$).

$$\beta = s \times t \quad \dots (15)$$

In order to correspond to the sampling points of the image data D2, the blend ratio determination unit 9 converts the eigenvalues λ_1 and λ_2 based on the sampling points of the image data D1 into eigenvalues based on the sampling points of the image data D2, and calculates a weighting coefficient α for blending. In this case, after a weighting coefficient α for blending is calculated from the sampling points of the image data D1, a weighting coefficient α for blending based on the sampling points of the image data D2 may be calculated by interpolation processing for the calculation result. In contrast, after the eigenvalues λ_1 and λ_2 based on the sampling points of the image data D2 are calculated by interpolating the eigenvalues λ_1 and λ_2 based on the sampling points of the image data D1, a weighting coefficient β for blending based on the sampling points of the image data D2 may be calculated from the calculation result.

The blend processing unit 10 performs weighting addition of image data S3 based on the pixel value P_{cc} calculated by the edge gradient direction processing unit 7 and image data S11 based on the pixel value P_a calculated by the interpolation processing unit 8 using the weighting coefficient β obtained by the blend ratio determination unit 9 by performing arithmetic processing represented by the

next condition, and outputs the processing result as the image data D2.

$$S4 = \beta \times S3 + (1 - \beta) \times S11 \quad \text{.....(16)}$$

(2) Operation of Embodiment

5 With the foregoing configuration, the input image data D1 (Fig. 1) is input to the edge detection unit 2. In the edge detection unit 2, the edge gradient direction v1 with the largest gradient of pixel values and the edge direction v2 orthogonal to the edge gradient direction v1 are
10 sequentially detected for each pixel (Figs. 2 and 3). In addition, the input image data D1 is input to the edge direction processing unit 5. In the edge direction processing unit 5, the image data is smoothed in the edge direction v2 for each pixel of the output image data D2 in
15 accordance with a detection result of the edge detection unit 2, and a pixel value Pc corresponding to each pixel of the output image data D2 is sequentially calculated. In addition, the pixel value Pc is input to the edge gradient direction processing unit 7 in accordance with a calculation
20 result. In the edge gradient direction processing unit 7, in accordance with the detection result of the edge detection unit 2, edge enhancement is performed in the edge gradient direction v1 for each pixel of the output image data D2, and a pixel value of the output image data D2 is

calculated. Accordingly, since the input image data D1 is smoothed in the edge direction v2, occurrence of jaggies can be effectively avoided. In addition, edge enhancement is performed in the edge gradient direction v1 orthogonal to the edge direction v2. Thus, high-frequency components are enhanced in the direction orthogonal to the edge direction. Therefore, conversion into the image data D2 is performed while effectively avoiding loss of high-frequency components and preventing occurrence of jaggies.

By performing a series of processing as described above, concerning the input image data D1, in the edge direction processing unit 5 (Fig. 4), interpolated image data Pc in the edge direction based on interpolation processing for the input image data D1 is generated for each pixel of the output image data D2 on a line extending in the edge direction v2 in accordance with a detection result of the edge detection unit 2, and the pixel value Pc' corresponding to each pixel of the output image data D2 is sequentially calculated by filtering processing of the interpolated image data Pc in the edge direction generated as described above. Accordingly, by setting a characteristic for the filtering processing, smoothing processing is performed in the edge direction v2, and occurrence of jaggies can be effectively avoided.

Concerning the input image data D1, in the edge

detection unit 2, the gradient matrix generation unit 3 generates a brightness gradient matrix G for each pixel, and the subsequent eigenvalue and eigenvector detection unit 4 processes this brightness gradient matrix G to detect the edge gradient direction $v1$ and the edge direction $v2$. At the same time, the eigenvalues $\lambda1$ and $\lambda2$ representing dispersions of pixel value gradients for the edge gradient direction $v1$ and the edge direction $v2$ are also calculated.

From among calculation results of the edge detection unit 2, for the eigenvalues $\lambda1$ and $\lambda2$, the ratio $\lambda2/\lambda1$ of the eigenvalue $\lambda2$ to the eigenvalue $\lambda1$ is calculated by the edge direction processing range determination unit 6. The ratio $\lambda2/\lambda1$ decreases as the pixel gradient in the edge gradient direction is more predominant. Accordingly, reliability of an edge is detected. Thus, in the edge direction processing range determination unit 6, the parameter p representing the reliability of the edge is generated in accordance with the ratio $\lambda2/\lambda1$ (Fig. 5). Thus, in this embodiment, the reliability of the edge is calculated by effectively using the gradient matrix g used for calculation of the edge gradient direction $v1$ and the edge direction $v2$. In addition, since the eigenvalue $\lambda1$ represents the strength of the edge, the parameter q corresponding to the parameter p is generated in accordance with the eigenvalue $\lambda1$ (Fig. 6). In addition, the filtering

range r is calculated by multiplication of the parameters p and q .

Concerning the input image data $D1$, when the edge direction processing unit 5 performs filtering processing on the interpolated image data Pc in the edge direction to generate the pixel value Pc' of the output image $D2$, the number of taps for the filtering processing is changed in accordance with the filtering range r generated by the edge direction processing range determination unit 6 as described above. If the reliability of the edge is high, the pixel value Pc' of the output image data $D2$ is generated by performing filtering processing on the interpolated image data Pc in the edge direction in a wide range. If the reliability of the edge is low, the pixel value Pc' of the output image data $D2$ is generated by performing filtering processing in a narrow range. Thus, for the input image data $D1$, the number of taps for the filtering processing for the edge direction $v2$ is changed in accordance with the reliability of the edge. Thus, excessive smoothing processing in a portion other than the edge can be prevented, and a reduction in the image quality can be effectively avoided.

In addition, by performing smoothing processing as described above, for the image data $D1$, the weighting coefficient α for filtering processing is changed (condition

(12)) in accordance with the reliability of the edge in the edge direction v2. In addition, by performing weighting addition of filtering processing results with different numbers of taps using the weighting coefficient α (condition 5 (14)), the number of taps is changed in a decimal fractional part. Thus, unnaturalness in changing the integral number of taps is overcome.

Concerning the image data obtained by calculation in the edge direction processing unit 5, in the edge gradient direction processing unit 7, in accordance with a detection 10 result of the edge detection unit 2, interpolated image data Pcc in the edge gradient direction obtained by interpolation processing for the image data based on the pixel values output from the edge direction processing unit 5 is 15 generated for each pixel of the output image data D2 on a line extending in the edge gradient direction v1 (Fig. 7), and the pixel value Pcc' of the output image data D2 is calculated by performing filtering processing of the interpolated image data Pcc in the edge gradient direction. 20 Accordingly, by setting a characteristic for the filtering processing, edge enhancement is performed in the edge gradient direction v1, and the image data D2 is generated.

For output data of the edge gradient direction processing unit 7 generated as described, however, when the 25 image data D1 based on a natural image is processed, the

outline may be excessively enhanced. Thus, for the image data D1, the interpolation processing unit 8 calculates a pixel value Pa' for each pixel of the output image data D2 by interpolation processing in accordance with a known
5 procedure. Accordingly, although high-frequency components of the image data S11 generated by the interpolation processing unit 8 based on the known procedure are lost, the outline of the image data S11 is not excessively enhanced.

For the image data D1, the blend processing unit 10
10 performs weighting addition of the image data S11 from the interpolation processing unit 8 and the image data S3 from the edge gradient direction processing unit 7 in accordance with an image to generate the output image data D2. Thus, a portion in which the outline is excessively enhanced is
15 corrected using a pixel value Pa' in accordance with the known procedure, and the output image data D2 is generated. Therefore, in this embodiment, a reduction in the image quality due to excessive edge enhancement can be prevented.

In this embodiment, similarly to a case where the
20 filtering range r is calculated in the edge direction processing range determination unit 6, the reliability of an edge is calculated using the ratio λ_2/λ_1 of the eigenvalue λ_2 to the eigenvalue λ_1 , and the weighting coefficient β for weighting addition performed in the blend processing unit 10
25 is calculated in accordance with the reliability of the edge

(Fig. 8). In addition, the weighting coefficient β is corrected using the eigenvalue λ_1 (Fig. 9). Thus, in this embodiment, in such processing for preventing excessive edge enhancement, the gradient matrix g used for calculating the edge gradient direction v_1 and the edge direction v_2 is effectively used to calculate the reliability of the edge, and the weighting coefficient β is set in accordance with the reliability of the edge. Thus, excessive edge enhancement can be prevented with such a simplified configuration.

(3) Effects of Embodiment

With the foregoing configuration, the edge gradient direction v_1 with the largest gradient of pixel values and the edge direction v_2 orthogonal to the edge gradient direction v_1 are detected, and edge enhancement and smoothing processing are performed in the edge gradient direction v_1 and the edge direction v_2 , respectively, to generate the output image data D_2 . Thus, loss of high-frequency components can be effectively avoided and occurrence of jaggies can be prevented.

In filtering processing for such smoothing processing, after the interpolated image data P_c in the edge direction obtained by interpolation processing for the input image data D_1 is generated for each pixel of the output image data D_2 on a line extending in the edge direction v_2 in

accordance with a detection result of the edge detection unit 2, the pixel value P_c' corresponding to each pixel of the output image data D2 is sequentially detected by performing filtering processing of the interpolated image data P_c in the edge direction. Accordingly, a characteristic for the filtering processing is variously set, and smoothing processing with a desired characteristic can thus be performed.

In addition, the number of taps for the filtering processing is changed in accordance with the reliability of the edge in the edge direction v_2 . Thus, incorrect smoothing processing in a portion other than the edge can be prevented.

In addition, the weighting coefficient α for the filtering processing is changed in accordance with the reliability of the edge in the edge direction v_2 , and the number of taps is changed in a decimal fractional part by performing weighting addition of filtering processing results of different numbers of taps using the weighting coefficient α for the filtering processing. Thus, by changing the number of taps as described above, unnaturalness in changing the integral number of taps can be effectively avoided.

In addition, since the reliability of the edge in the edge direction v_2 is the ratio of the dispersion λ_2 of the

pixel value gradient in the edge direction v2 to the dispersion λ_1 of the pixel value gradient in the edge gradient direction v1, the configuration for detecting the edge gradient direction v1 and the edge direction v2 is effectively used, and unnaturalness in changing the number of taps can be effectively prevented.

In contrast, after the interpolated image data Pcc in the edge gradient direction obtained by interpolation processing for the image data Pc based on the pixel value Pc' output from the edge direction processing unit 5 is generated for each pixel of the output image data D2 on a line extending in the edge gradient direction v1 in accordance with a detection result of the edge detection unit 2, processing of edge enhancement is performed by filtering processing of the interpolated data Pcc in the edge gradient direction. Thus, a characteristic for the filtering processing is variously set, and edge enhancement with a desired characteristic can thus be performed.

In addition, a series of processing is performed such that a sampling pitch in the output image data D2 is different from a sampling pitch in the input image data D1, and sampling pitches are changed together in smoothing processing and edge enhancement processing. The interpolation processing unit 8 converts the input image data D1 into the interpolated image data S11. The weighting

coefficient β for blending is changed in accordance with the reliability of the edge in the edge direction v_2 . Weighting addition of the image data S_3 output from the edge gradient direction processing unit and the interpolated image data

5 S_{11} is performed in accordance with the weighting coefficient β for blending, and the output image data D_2 is output. Accordingly, excessive edge enhancement in a natural image can be effectively prevented.

(4) Other Embodiments

10 Although a case where a smoothing processing range in an edge direction is changed in accordance with a change of the number of taps has been described in the foregoing embodiment, the present invention is not limited to this. The number of taps may be equally changed in accordance with
15 a change in a weighting coefficient for smoothing processing.

In addition, although a case where a smoothing processing range and weighting addition performed in the blend processing unit are changed in accordance with the ratio of the eigenvalue λ_2 to the eigenvalue λ_1 and the
20 eigenvalue λ_1 has been described in the foregoing embodiment, the present invention is not limited to this. When a practically sufficient characteristic can be ensured, such changes may be made in accordance with only the ratio of the eigenvalue λ_2 to the eigenvalue λ_1 . In addition, instead of
25 detection of the reliability of the edge in accordance with

the ratio of the eigenvalue λ_2 to the eigenvalue λ_1 and the eigenvalue λ_1 , various edge detection methods may be applied. In addition, since excessive edge correction for weighting addition performed by the blend processing unit occurs in a point, for example, in which leaves of a tree grows close together, in a natural image, such changes may be made in accordance with, for example, a characteristic of each portion of the image detected as a frequency characteristic or the like.

10 In addition, although a case where a smoothing processing range and weighting addition performed by the blend processing unit are changed has been described in the foregoing embodiment, the present invention is not limited to this. When a practically sufficient characteristic can be ensured, such processing may be omitted. Moreover, one of such processing or both of such processing may be omitted depending on the type of an image.

In addition, although a case where an image is magnified or reduced by changing a sampling pitch in the input image data D1 has been described in the foregoing embodiment, the present invention is not limited to this. The present invention is also widely applicable to processing for edge correction. In this case, in the edge direction processing unit and the edge gradient direction processing unit, a series of processing is performed in

20

25

accordance with a sampling pitch of output image data that is equal to a sampling pitch of the input image data. In addition, the configuration for interpolation processing is omitted, and the blend processing unit 10 performs weighting
5 addition of output data of the edge gradient direction processing unit 7 and the input image data. Thus, edge enhancement of input image data can be simply performed.

In addition, although a case where arithmetic processing means performs a predetermined program to process
10 image data has been described in the foregoing embodiment, the present invention is not limited to this. The present invention is also widely applicable to a case where image data is processed with hardware configuration.

15 Industrial Applicability

The present invention is applicable, for example, to resolution conversion.
